Subject: UCD

Class: TY-CORE6

Assignment-5

Q1. What is UI evaluation? Discuss its Two Broad categories.

→ UI evaluation is the process of assessing the usability and functionality of a user interface to ensure it meets user needs and delivers a positive experience. It is broadly categorized into Analytical Evaluation and Empirical Evaluation.

1. Analytical Evaluation:-

It relies on experts to review the interface based on usability principles, such as heuristic evaluation, cognitive walkthroughs, and guideline reviews. This approach is cost-effective and helps identify design flaws early. However, it may not fully capture actual user behaviour or preferences.

2. Empirical Evaluation:-

It involves real users interacting with the interface in scenarios like usability testing, A/B testing, or feedback collection through surveys. This method provides actionable insights into user behavior and satisfaction but

requires more time, efforts, and resources to execute effectively.

By combining these methods, designers can balance expert-driven insights ~~and~~ with real-world user feedback, ensuring the interface is functional, user-friendly, and aligned with user expectations.

Q2. What is Formative and Summative Testing.

Explain with example.

→ Formative and Summative Testing are two key approaches to evaluating usability in the development of a product or UI.

Formative Testing :-

This type of testing is conducted during the early stages of development to identify usability issues and areas for improvement.

It focuses on diagnosing problems and enhancing the design iteratively. The goal is to refine the product before significant resources are invested.

Example:- In developing a mobile banking app, formative testing might involve observing users as they navigate an initial prototype to complete tasks like transferring money or checking

account balances. Feedback from this stage helps developers improve navigation and interface clarity before finalizing the design.

2. Summative Testing :-

This testing occurs at the end of the development process to evaluate the product's overall usability and performance against predefined metrics or goals. It focuses on validating the final design.

Example :- For the same mobile banking app, summative testing could involve giving the fully developed app to a group of users to measure task completion rates, error rates, and satisfaction levels. The results help determine whether the app is ready for release.

Both testing types complement each other: formative testing ensures iterative improvement while summative testing validates the final product's effectiveness.
